# 2 Alternating properties of projective locus

**Theorem 2.1** (Alternating property of projective locus, see [Kol22b], Proposition 17). Let  $g: X \to S$  be a proper morphism of normal, irreducible analytic spaces. Then there is a dense, Zariski open subset  $S^{\circ} \subset S$  such that

- (1) either X is locally projective over  $S^{\circ}$ ,
- (2) or  $\operatorname{PR}_S(X) \cap S^{\circ}$  is locally contained in a countable union of Zariski closed, nowhere dense subsets.

*Proof.* The main technical tool is the sheaf exponential sequence with its restriction on the fiber.

# 3 Alternating property of very big locus, general type locus

We begin this section by defining very big locus, general type locus and Moishezon locus.

**Definition 3.1** (Very big locus, general type locus, Moishezon locus, see [Kol22a] Definition 18). Let  $g: X \to S$  be a proper morphism of normal analytic spaces and L a line bundle on X. Set

- 1.  $VB_S(L) := \{ s \in S : L_s \text{ is very big on } X_s \} \subset S$ ,
- 2.  $GT_S(X) := \{ s \in S : X_s \text{ is of general type } \} \subset S$ ,
- 3.  $MO_S(X) := \{ s \in S : X_s \text{ is Moishezon } \} \subset S$ ,
- 4.  $PR_S(X) := \{ s \in S : X_s \text{ is projective } \} \subset S$ .

here very big means the place  $s \in S$  that

$$X_s \dashrightarrow \operatorname{Proj}_S(g_*L_s) = (\operatorname{Proj}_S(g_*L))_s$$

is birational onto its closure of the image.

We first show that the very big locus satisfies an alternating property; that is, it is either nowhere dense or contains a dense open subset.

**Theorem 3.2** (Alternating property for very big locus, see [Kol22a] Lemma 19).

Let  $g: X \to S$  be a proper morphism of normal irreducible analytic spaces(and therefore S is integral) and L a line bundle on X. Then  $VB_S(L) \subset S$  is

- (1) either nowhere dense (in the analytic Zariski topology),
- (2) or it contains a dense open subset of S, and  $g: X \to S$  is Moishezon.

*Proof.* By passing to an open subset of S, we may assume that g is flat,  $g_*L$  is locally free and commutes with restriction to fibers. We get a meromorphic map  $\phi: X \dashrightarrow \mathbb{P}_S(g_*L)$ . There is thus a smooth, bimeromorphic model  $\pi: X' \to X$  such that  $\phi \circ \pi: X' \to \mathbb{P}_S(g_*L)$  is a morphism.

After replacing X by X' and again passing to an open subset of S, we may assume that g is flat,  $g_*L$  is locally free, commutes with restriction to fibers, and  $\phi: X \to \mathbb{P}_S(g_*L)$  is a morphism. Let  $Y \subset \mathbb{P}_S(g_*L)$  denote its image and  $W \subset X$  the Zariski closed set of points where  $\pi: X \to Y$  is not smooth. Set  $Y^\circ := Y \setminus \phi(W)$  and  $X^\circ := X \setminus \phi^{-1}(\phi(W))$ . The restriction  $\phi^\circ: X^\circ \to Y^\circ$  is then smooth and proper.

We assume that  $\phi^{-1}(y)$  is a single point for a dense set in Y, hence for a dense set in  $Y^{\circ}$ . Since  $\phi^{\circ}$  is smooth and proper, it is then an isomorphism. Thus  $\phi$  is bimeromorphic on every irreducible fiber that has a nonempty intersection with  $X^{\circ}$ .

As a direct consequence (combined with the classical result by Hacon and Mckernan [**HaconMckernan**]) we have the general type locus also admits alternating property.

**Theorem 3.3** (Alternating property for general type locus, see [Kol22a] Corollary 20). Let  $g: X \to S$  be a proper morphism of normal, irreducible analytic spaces. Then

$$GT_S(X) = \{ s \in S \mid X_s \text{ is of general type} \}$$

(1) either nowhere dense (in the analytic Zariski topology), (2) or it contains a dense open subset of S, and  $g: X \to S$  is Moishezon

*Proof.* Proof. Using resolution of singularities, we may assume that X is smooth. By passing to an open subset of S, we may also assume that  $\underline{S}$  and g are smooth. By [**HaconMckernan**] there is an m (depending only on dim  $X_s$ ) such that  $|mK_{X_s}|$  is very big whenever  $X_s$  is of general type. Thus Lemma 3.2 applies to  $L = mK_X$ .

Today we will continue our discussion on the paper Moishezon morphism. We will first finish our discussion on the Moishezon locus, we will prove a interesting locally freeness result about the direct image sheaves. Then we will delve into today's main topic, the proof of the Conjecture 5 with additional assumptions that the central fiber is KLT and not uniruled.

#### 4 The alternating property of Moishezon locus

Before proving Theorem 21. Let us first recall the basic idea that being used in [RT22]

**Theorem 4.1** (Uncoutnable many fibers are Moishezon with deformation invariance of Hodge number implies the morphism is Moishezon, see [RT22] Proposition 3.15).

Let  $\pi: \mathcal{X} \to \Delta$  be a one-parameter degeneration. (1) Assume that there exists an uncountable subset B of  $\Delta$  such that for each  $t \in B$ , the fiber  $X_t$  admits a line bundle  $L_t$  with the property that  $c_1(L_t)$  comes from the restriction to  $X_t$  of some cohomology class in  $H^2(\mathcal{X}, \mathbb{Z})$ . (2) Assume further that the Hodge number  $h^{0,2}(X_t) := h^1(X_t, \mathcal{O}_{X_t})$  is independent of  $t \in \Delta$  (the original theorem require only Hodge (0,1) deformation invariance)

*Proof.* Apply the sheaf exponential exact sequence so that

$$\longrightarrow H^{1}(\mathcal{X}, \mathcal{O}_{\mathcal{X}}^{*}) \longrightarrow H^{2}(\mathcal{X}, \mathbb{Z}) \xrightarrow{e_{2}} H^{2}(\mathcal{X}, \mathcal{O}_{X}) \longrightarrow$$

$$\downarrow \qquad \qquad \downarrow \qquad \qquad \longrightarrow H^{1}(X_{s}, \mathcal{O}_{X_{s}}^{*}) \longrightarrow H^{2}(X_{s}, \mathbb{Z}) \xrightarrow{e_{2}} H^{2}(X_{s}, \mathcal{O}_{X_{s}}) \longrightarrow$$

Observe that

$$H^2(\mathcal{X}, \mathcal{O}_{\mathcal{X}}) \cong R^2 \pi_* \mathcal{O}_{\mathcal{X}}(\Delta), \ H^2(X_s, \mathcal{O}_{X_s}) \cong R^2 \pi_* \mathcal{O}_{\mathcal{X}}(s)$$

Indeed

(1) By Cartan B. we have

$$H^{p}(S, R^{q}\pi_{*}\mathcal{O}_{X}) = 0, \ p > 0$$

the Leray spectral sequence arguement thus implies the first isomorphism, (2) Since we assume the cohomological constant of  $h^{0,2}$ , by Grauert base change theorem it will imply the second isomorphism.

Thus the commutative diagram becomes

Where we have the evaluation  $\text{ev}_s: H^0(\mathcal{X}, R^2\pi_*\mathcal{O}_{\mathcal{X}}) \to R^2\pi_*\mathcal{O}_{\mathcal{X}}(s)$  in the diagram above.

The idea is to find a cohomology class  $c \in H^2(X_s, \mathbb{Z})$  by the simply connectness of  $\Delta$  it will lift it to  $c \in H^2(\mathcal{X}, \mathbb{Z})$ , if we can prove the vanishing of  $e_2(c) \in H^2(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$  then by the exactness of the sequence we can find some global line bundle  $\mathcal{L} \in \text{Pic}(\mathcal{X})$ .

Observe that the cohomology group  $H^2(X_s, \mathbb{Z}) \cong H^2(\mathcal{X}, \mathbb{Z})$  by Ehresmann's theorem, and this  $\mathbb{Z}$  coefficient cohomology group can only have counable many elements, taking uncountble many  $L_t$ , it must have some  $c \in H$  such that there is uncountable many t such that  $c_1(L_t) = c$ .

Since this  $c \in H^2(X_s, \mathbb{Z})$  coming from  $\operatorname{Pic}(X_s)$ , we have  $e_2(c) = 0 \in R^2\pi_*\mathcal{O}_{\mathcal{X}}(s)$  and thus if we lift it to  $c \in H^2(\mathcal{X}, \mathbb{Z})$  the global section  $e_2(c) \in H^0(\mathcal{X}, R^2\pi_*\mathcal{O}_{\mathcal{X}})$  it will be zero on uncounable many points. Thus by the identity principle easy to see  $e_2(c) = 0 \in H^2(\mathcal{X}, R^2\pi_*\mathcal{O}_{\mathcal{X}})$ . Thus thus lift to some global line bundle  $\mathcal{L} \in \operatorname{Pic}(\mathcal{X})$  with the restriction  $c_1(\mathcal{L}|_{X_s}) = c_1(L_s)$  and we can now apply the lemma about deformation density of Iitaka-Kodaira dimension below and conclude that  $\mathcal{L}$  is indeed a big line bundle to finish the proof.

Now let's going into the proof of alternating property of Moishezon locus

**Theorem 4.2** ([Kol22a, Theorem 21]). Let  $g: X \to S$  be a smooth, proper morphism of normal, irreducible analytic spaces. Then  $MO_S(X) \subset S$  is

- (1) either contained in a countable union  $\cup_i Z_i$ , where  $Z_i \subseteq S$  are Zariski closed,
- (2) or  $MO_S(X)$  contains a dense, open subset of S.

Furthermore, if  $R^2g_*\mathcal{O}_X$  is torsion free then (2) can be replaced by

(3)  $MO_S(X) = S$  and g is locally Moishezon.

Proof.

Theorem 4.3 (Deformation density of Iitaka-Kodaira dimension, see [LiebermanSernesi; RT22]).

Let  $\pi: \mathcal{X} \to Y$  be a flat family from a complex manifold over a one-dimensional connected complex manifold Y with possibly reducible fibers.

If there exists a holomorphic line bundle L on  $\mathcal{X}$  such that the Kodaira-Iitaka dimension  $\kappa\left(L_{t}\right)=\kappa$  for each t in an uncountable set B of Y, then any fiber  $X_{t}$  in  $\pi$  has at least one irreducible component  $C_{t}$  with  $\kappa\left(L_{C_{t}}\right) \geq \kappa$ .

In particular, if any fiber  $X_t$  for  $t \in Y$  is irreducible, then  $\kappa(L_t) \geq \kappa$ .

We first prove an interesting locally freeness criterion for direct image sheaves.

**Theorem 4.4** (locally freeness criterion for  $R^i f_* \mathcal{O}_X$ , see [Kol22a], Theorem 24). Let  $f: X \to S$  be a smooth, proper morphism of analytic spaces. Assume that  $H^i(X_s, \mathbb{C}) \to H^i(X_s, \mathcal{O}_{X_s})$  is surjective for every i for some  $s \in S$ . Then  $R^i g_* \mathcal{O}_X$  is locally free in a neighborhood of s for every i.

*Proof.* We begin our proof by noticing by the direct image theorem it's enough to show the surjectivity of the base change morphism

$$\phi_s^i: R^i f_* \mathcal{O}_X \to H^i (X_s, \mathcal{O}_{X_s})$$

for every i.

Indeed the base change theorem shows that the surjectivity of the base change morphisms  $\phi_s^i$  and  $\phi_s^{i-1}$  implies the locally freeness of the direct image  $R^i f_*(\mathcal{O}_X)$ .

Next by the Theorem on Formal Functions, it is enough to prove this when S is replaced by any Artinian local scheme  $S_n$ , whose closed point is s.

By Cartan B easy to see the vanishing of  $H^p(S_n, R^i f_* \mathcal{O}_X) = 0$ ,  $\forall q, \forall p > 0$  then by the Leray spectral sequence argument we get

$$H^{0}\left(S_{n}, R^{i} f_{*} \mathcal{O}_{X}\right) = H^{i}\left(X_{n}, \mathcal{O}_{X_{n}}\right)$$

On the affine base the fiber of the coherent sheaf is indeed the global section, as a consequence

$$R^{i}f_{*}\mathcal{O}_{X}(s) = H^{0}(S_{n}, R^{i}f_{*}\mathcal{O}_{X}) = H^{i}(X_{n}, \mathcal{O}_{X_{n}})$$

The base change morphism thus becomes

$$\psi^{i}: H^{i}\left(X_{n}, \mathcal{O}_{X_{n}}\right) \to H^{i}\left(X_{s}, \mathcal{O}_{X_{s}}\right).$$

Let  $\mathbb{C}_{X_n}$  (resp.  $\mathbb{C}_{X_s}$ ) denote the sheaf of locally constant functions on  $X_n$  (resp.  $X_s$ ) and  $j_n: \mathbb{C}_{X_n} \to \mathcal{O}_{X_n}$  (resp.  $j_s: \mathbb{C}_{X_s} \to \mathcal{O}_{X_s}$ ) the natural inclusions. We have a commutative diagram

$$H^{i}(X_{n}, \mathbb{C}_{X_{n}}) \xrightarrow{\alpha^{j}} H^{i}(X_{s}, \mathbb{C}_{X_{s}})$$

$$\downarrow j'_{s}$$

$$H^{i}(X_{n}, \mathcal{O}_{X_{n}}) \xrightarrow{\psi^{j}} H^{i}(X_{s}, \mathcal{O}_{X_{s}})$$

Note that  $\alpha^i$  is an isomorphism since the inclusion  $X_s \hookrightarrow X_n$  is a homeomorphism, and  $j_s^i$  is surjective since  $X_s$  is Du Bois. Thus  $\psi^i$  is also surjective.

Using this we can prove the theorem below

REFERENCES 6

**Theorem 4.5** (Fiberwise Moishezon morphism is locally Moishezon if it's smooth, see [Kol22a], Corollary 22). Let  $g: X \to S$  be a smooth, proper morphism of normal, irreducible analytic spaces whose fibers are Moishezon. Then g is locally Moishezon.

*Proof.* [Kol22a] Since we have proved the Moishezon manifolds admit strong Hodge decomposition, the morphism

$$H^i(X_s,\mathbb{C}) \to H^i(X_s,\mathcal{O}_{X_s})$$

is surjective for every i.

The result then follows clearly by 4.4 and [Kol22a] Theorem 21.
